Investigating the efficiency of Silicon Solar cells at different temperatures and wavelengths

By Shahzeen Attari

Physics 344 Electronic Circuits II (Digital Electronics)

Final Project 2003

Advisor: Professor Steven Errede

Abstract

In this project we develop and implement a data acquisition system to study the characteristics of silicon photovoltaic cells (solar cells). We vary the wavelength of light as well as the temperature of the solar cell to investigate how the open voltage across the cell varies with these parameters. This particular setup also allows fast data acquisition and is a stepping stone for further work that could investigate other parameters that affect the solar cell efficiency.

Introduction

There is a great need now to investigate the different forms of renewable energy and how to increase efficiency. We will soon find ourselves in an enormous energy crisis (after about 40 years) by that time we would need to depend on another source of energy. In order to maintain sustainable development as well as reduce environmental pollution we need to find a dependable 'clean energy' source that is cheap and easy to implement. Solar energy is very dependable but the cost of making the cells is too high for mass implementation at the moment. What we need to do is to increase solar cell efficiency and cheaper to make using new technologies. In this project my aim is to address the first issue. How can we make solar cells more efficient? In this work I look at the trend of the open source voltage at varying temperatures and wavelengths of light. This preliminary work will make a path for easy data acquisition and thereby opening the research to new parameters of study.

How does a solar cell work? A typical solar cell consists of a cover glass or other encapsulant, an anti-reflective layer, a front contact to allow the electrons to enter a circuit and a back contact to allow them to complete the circuit, and the semiconductor layers where the electrons begin and complete their voyages [1].

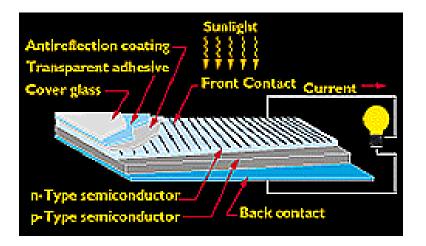

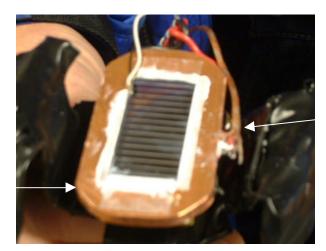

Figure 1. Schematics of a typical solar cell. The current flows from the p-type semiconductor to the n-type semiconductor and then through the circuit.

When the p-type and n-type semiconductors are placed on top of each other diffusion of a limited number of electrons and holes occurs, and a depletion region is formed. In this region, a small intrinsic voltage exists. Here if an electron moves into the conduction band it will be pushed away from the p-type and through the n-type material. A circuit is formed when leads are attached to the opposite sides of this p-n junction. In photovoltaic cells, the energy needed to boost an electron into the conduction band can be supplied by sunlight. In this manner solar energy is converted to electrical energy [2].

In this experiment we used a silicon solar cell (bought from radio shack no. 276-124). This solar cell was put onto a copper holder by first applying some thermally conduction, electrically insulating grease (thermal compound part no. 120-2, made by Wakefield Engineering INC.) A sheet of mica was placed between the copper and the solar cell to act as an electrical insulator. Two 250 power resistors were attached to the underside of the copper holder. This was done so that the temperature could be increased by the user. A small hole was drilled onto the side of the copper plate so that the temperature lead of the thermocouple could be in close proximity to the solar cell.

Thermocouple wire

Copper plate

Figure 2. The solar cell is attached to the copper plate using the grease.

A hole was drilled into the copper block to have a brass rod screwed into the middle of the plate. This was done so that the brass rod could be immersed in liquid nitrogen thereby conducting the heat away from the cell. The copper plate was then placed into a metal hammock that was covered with insulating tape. This was done so that the plate would not touch the liquid nitrogen Dewar.

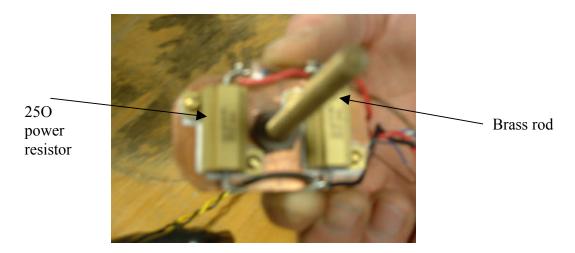

Figure 3. The underside of the copper plate showing the heating power resistors and the brass rod through the middle of the plate to conduct the heat away.

The entire setup was then placed into a liquid nitrogen Dewar:

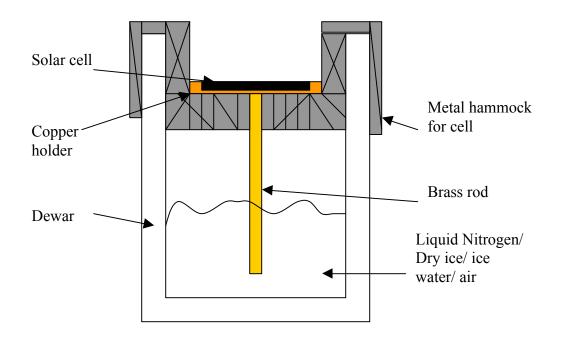

Figure 4. The setup of the solar cell in the liquid nitrogen Dewar. Inside the Dewar tried out a variety of coolers ranging from liquid nitrogen (-196°C), dry ice (-78.5°C), ice water (0°C) and air (22°C).

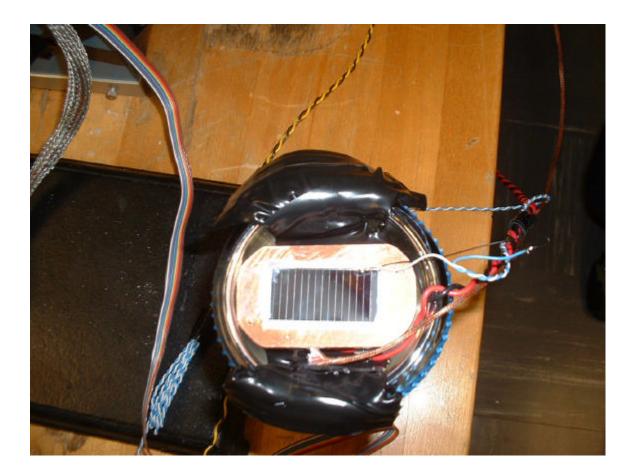

Figure 5. The top view of the solar cell setup. As you can see, the solar cell is not quite touching the Dewar. The leads coming out on the right of the picture are those belonging to the resistors, the solar cell and the thermocouple.

The thermocouple, as said earlier was used to measure the temperature of the copper block and thereby the temperature of the solar cell. We used copper and Constantine wires and exploited their different rates of thermal expansion to build our own thermocouple. The thermocouple was then connected to a 5B37 Analog devices thermocouple module. A variable power supply was used to supply power to the power resistors, this is user controlled.

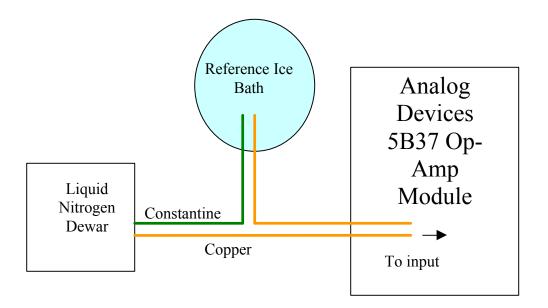

Figure 6. The schematics of the thermocouple used.

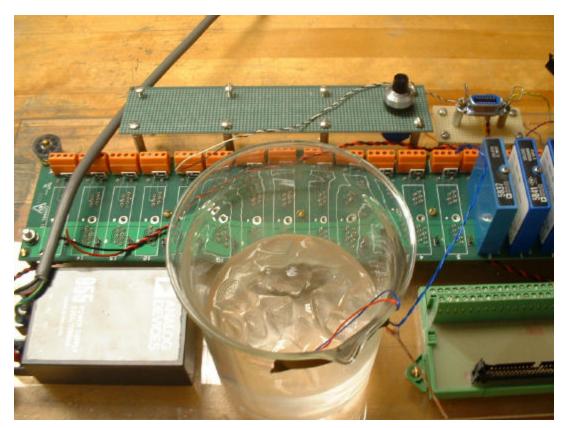

Figure 7. The ice bath used and the 5B37 Analog devices thermocouple module in the background.

A Chem Anal light source was used with a CM 3016 bulb, the light source is connected to a wavelength varying monochromator (also by Chem Anal). This device was then attached to a piece of Styrofoam that had a hole drilled through the center. This was done so that no water vapor could seep into the Dewar, and also to maintain constant temperature of the solar cell. All these leads were then hooked up to a circuit that had a feedback loop. The monochromator was hooked up to a stepper motor (SLO-SYN DC step motor M111) that would change the wavelength of light entering the solar cell. The Stepper motor was connected to a 12 volt power supply.

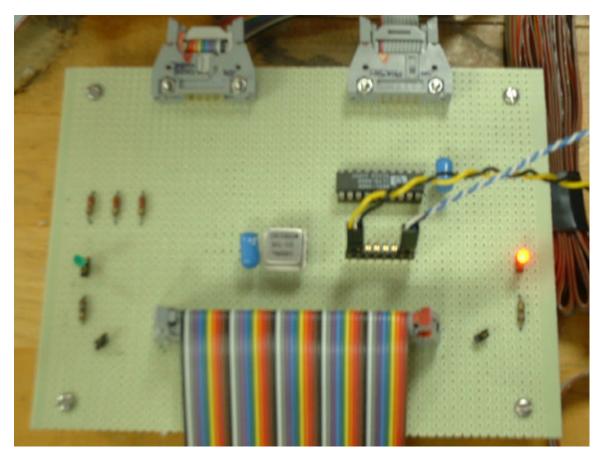

Figure 8. Circuit used to control the stepper motor as well as the phase on the 4 axis stepper motor control.

A power supply was used to provide 5v to the TTL components in the circuit. Please look at the attached circuit diagram for a better understanding of how the components are connected.

We used a DAQ Lab-PC+ which is a low-cost multifunction analog, digital, and timing I/O board for the PC [3].

In building the circuit we used

- 1) 50 pin 3M wire wrap connector, screws and washers
- 2) HP HCTL 2020 IC and a 20 pin wire socket
- 3) 1 MHZ quartz clock XTAL and a 14 pin wire wrap socket
- 4) 10-pin 3M 90° wire wrap connector and screws
- 5) 3 100 μ F @ 16 V dc capacitors
- 6) 1 green and 1 red mini LEDs and socket strip material
- 7) 1800 resistors
- 8) Vector board material and standoff screws

This circuit is similar to the one used in the lab experiment entitled "A PC-Based Torsional oscillator experiment for the physics 301 undergraduate classical mechanics and E&M laboratory course" [4].

Figure 9. The entire experimental setup showing the various power supplies and 4 Axis step motor driver on the left and the Dewar, monochromator and light source in the center and the variable power supply on the right.

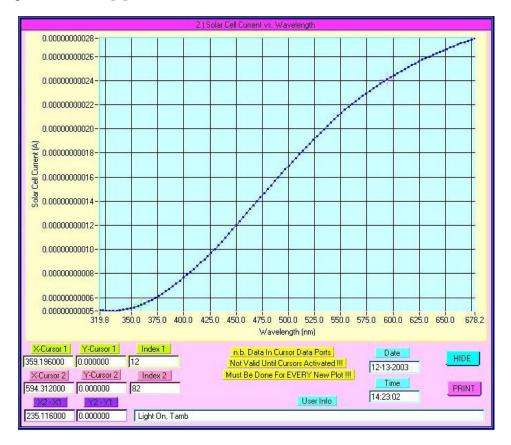

Professor Steven Errede wrote a computer program called Solar_Cell2.c that is an online DAQ program for the class. It uses National instruments Lab PC + I/O board and National instruments Lab Windows/CVI software

The Light source illumination the slit of the Chem Anal system diffraction grating spectrometer that is controlled by the 1.8 degree/step stepper motor is controlled by this program. It is directly coupled to the cam shift that changes the angle of the diffraction grating in the Chem Anal thereby scanning the visible wavelength spectrum (320 nm < ? < 680nm) by rotating the cam shaft.

The HP / Agilent HEDS-5540-A 06 code wheel encoder assembly is used to monitor the angular position of the stepper motor. The code wheel encoder has 500 counts / revolution readout. The HP / Agilent HCTL – 2020 16 bit up/down counter IC does a 4x sampling of the (90°) quadrature signals from the code-wheel assembly, therefore there are 2000 counts per revolution.

The stepper motor used in this experiment has 200 steps per revolution. The 4 phases (A, B, C, D) define the rotation. If you want a clockwise cycle, a sequence of 4 steps e.g. phase A, then phase B, then phase C and then D. Id you want a counter clockwise step, first move phase D, then C, then B and then A.

A 500 count / revolution optical code wheel is attached to the shaft of the Stepper motor to monitor the angular position of the stepper motor. The code wheel is read out by the HP HCTL -2020 16 bit up/down counter chip, that decodes the quadrature signals from the code wheel, using the 4x decoding. Thus, there are a total of 2000 (=4*500) decoder counts per revolution [5].

Figure 12. A sample data set from the program. At the head of the file the following data is also included:

c:\cvi\P344\Data\SC2_Light_On_Air_T44C_Gain10.txt DAQ PROGRAM: Solar_Cell2.prj Time: 16:52:33

The data can be imported into MS Excel and analyzed:

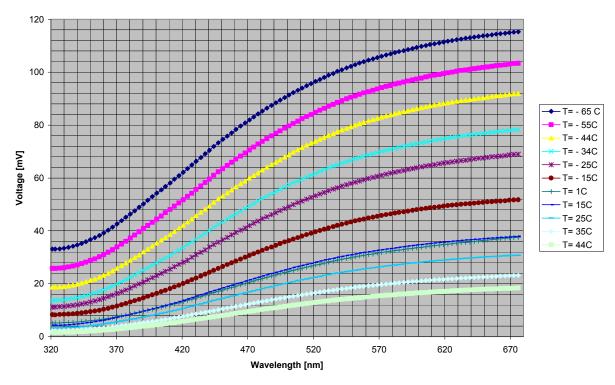

Figure 13. Data analyzed from the computer program

From this result we find that the voltage across the solar cell is very dependent on the wavelength. This is due to the fact that the light source does not have constant output intensity. We also find that the voltage increases with a decrease in temperature.

We then used an IL700 Radiometer/Photometer to calculate the light intensity of the bulb.

| W (nm) | V_sc (mV) | T_sc (C) | V_rp (mV) | I_rp(uW/cm ²) |

Ealing Radiometer/Photometer Absolute Intensity vs. Wavelength

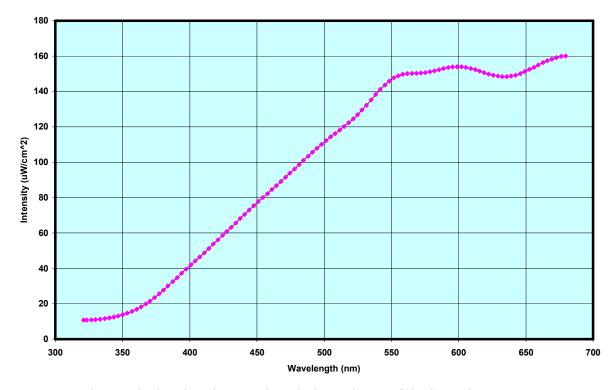

Figure 14. The graph showing the wavelength dependence of the intensity.

Note that since the solar cell was not hooked up for the calibration data-taking, nor was the thermocouple electronics powered on. The reason for this wavelength dependence could be the fact that the CM-1601 light gives off a black-body spectrum, and there are also some wiggles in the intensity curve at longer wavelengths, which may be due to e.g. wavelength-dependent reflection/transmission/absorption associated with the optics/lenses in the Chem Anal Diffraction Grating Spectrometer

In order to normalize the previous data from the solar cell we need to use this formula:

$$V_solarcell(1_normalised) = V_solarcell(1) \times \frac{Intensity(1_reference)}{Intensity(1)}$$

I am choosing the reference wavelength as 600 nm, the intensity at ? reference is $153.279602 \text{ uW/cm}^2$. Therefore we need to multiply the data by a new value:

| Intensity/intensity_reference | W (nm) |
|-------------------------------|---------|
| 14.30698112 | 320.936 |

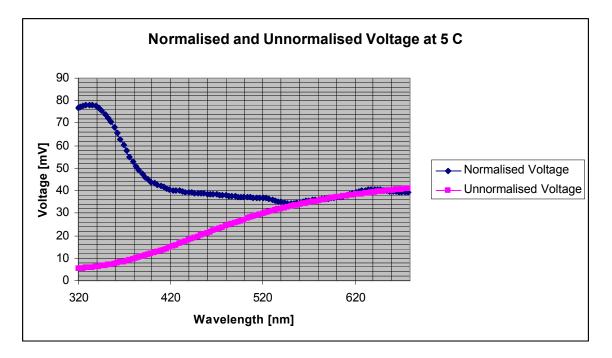

Figure 15. The normalized voltage and the unnormalised voltage vs. wavelength of light

The initial squiggles may be attributed to the fact that we simply chose 600 nm as our reference. But the normalized curve does flatten out. It is this value of voltage we are interested in.

In conclusion: primarily this semester was spent trying to build the system and making sure that it worked. The results obtained show explicitly that the amount of voltage produced across the solar cell is indeed increased by a temperature drop. In order to investigate the problem further we will need to understand some fundamentals about sunlight and experiment with varying the intensity of the light the solar cell is exposed to.

If the efficiency of solar cells are increased it would mean more energy for the same cost as before. This would make more people interested in the "clean energy option". The results of this experiment show that if we could some how reduce the temperature of the solar cell and keep it there, we could produce more energy. Further research has to be carried out to investigate different transparent insulators as well as other variables that could possibly affect the solar cell.

Acknowledgments: I would like to thank Professor Steven Errede whose guidance, dedication and patience made this project possible. His wonderful program was essential in rapid data acquisition and his mastery of electronics helped in designing the circuits used for this project. I would also like to thank Jack Boparai who helped me obtain all the required tools and devices needed for this experiment. Lastly, I would like to thank Micah Yairi whose paper 'Solar Cell Efficiency' written for class in 1993 helped pave the way for this project.
